

PHYS 350 Formula Sheet

Lagrangian Mechanics

Hamilton's Principle: $\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t)$ minimizes

$$\mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) \rightarrow S[t] = \int_{t_1}^{t_2} \mathcal{L}(\mathbf{q}, \dot{\mathbf{q}}, t) dt$$

Euler-Lagrangian Equation:

$$\frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{q}_i} \right) - \frac{\partial \mathcal{L}}{\partial q_i} = 0 \quad i = 1, 2, \dots, s$$

Conservation of Energy:

$$\frac{\partial \mathcal{L}}{\partial t} = 0$$

$$E = T + U = \sum_{i=1}^s q_i \frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \mathcal{L}$$

Conservation of Momentum:

$$\frac{\partial \mathcal{L}}{\partial q_i} = 0$$

$$p_i = \frac{\partial \mathcal{L}}{\partial \dot{q}_i}$$

Systems with $s = 1$, $\frac{\partial \mathcal{L}}{\partial t} = 0$:

- $\mathcal{L}(q, \dot{q}) = \frac{\alpha(q)\dot{q}^2}{2} - U(q)$
- $E \geq U(q)$
- $U(q_0) = E$ are turning points
- $\int_0^T dt = \int_0^Q \frac{1}{\sqrt{\frac{2}{\alpha(q)}(E - U(q))}} dq$

Two Body Problem

Generalized Coordinates:

$$\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2$$

$$\mathbf{R}_{\text{CM}} = \frac{m_1 \mathbf{r}_1 + m_2 \mathbf{r}_2}{m_1 + m_2}$$

$$\mathbf{r}_1 = \frac{m_2}{m_1 + m_2} \mathbf{r} + \mathbf{R}_{\text{CM}} \quad \mathbf{r}_2 = -\frac{m_1}{m_1 + m_2} \mathbf{r} + \mathbf{R}_{\text{CM}}$$

Lagrangian:

$$\mathcal{L} = \frac{\mu}{2} |\dot{\mathbf{r}}|^2 + \frac{M}{2} |\dot{\mathbf{R}}_{\text{CM}}|^2 - U(\mathbf{r})$$

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \quad M = m_1 + m_2$$

Reduction to independent problems:

$$\mathcal{L} = \mathcal{L}_{\text{CM}} + \mathcal{L}_{\text{rel}}$$

$$\mathcal{L}_{\text{CM}} = \frac{M}{2} |\dot{\mathbf{R}}_{\text{CM}}|^2$$

$$\mathcal{L}_{\text{rel}} = \frac{\mu}{2} |\dot{\mathbf{r}}|^2 - U(\mathbf{r})$$

Angular Momentum in Polar Coordinates:

$$\ell = \mu r^2 \dot{\phi}$$

Planetary Motion

$$U(r) = -\frac{Gm_1 m_2}{r} = -\frac{\alpha}{r}$$

Eccentricity when $\ell \leq 0$:

$$e = \sqrt{1 + \frac{E_{\text{rel}}}{U_o}} \quad U_o = |\min\{U_{\text{eff}}(r)\}|$$

$$\text{Trajectory} = \begin{cases} \text{Constant radius orbit} & e = 0 \\ \text{Ellipse} & 0 < e < 1 \\ \text{Parabola} & e = 1 \\ \text{Hyperbola} & e > 1 \end{cases}$$

Small Oscillations

Equilibrium Point:

$$\left. \frac{dU}{dq} \right|_{q=q_0} = 0$$

Stability Criterion of Equilibrium Point ($s = 1$):

$$\frac{d^2 U}{dq^2} > 0$$

Stability Criterion of Equilibrium Point ($s \geq 2$):

$$\frac{\partial^2 U}{\partial q_i \partial q_j} = K_{ij} = K_{ji} \geq 0$$

Small Angle Approximation:

Taylor expand around equilibrium point of the Lagrangian q_0 and keep up to first term that contributes to the Lagrangian.

General Solution to $\ddot{x} = -\omega^2(x - x_0) + f(t)$:

$$\text{Let } z(t) = \dot{x}(t) + i\omega x(t) \quad x(t) = x_0 + \text{Im}\{z(t)\}/\omega$$

$$z(t) = e^{i\omega t} \left[z(0) + \int_0^t e^{-i\omega \tau} f(\tau) d\tau \right]$$

Rigid Body Motion

Kinetic Energy:

$$T = \frac{M}{2} |\mathbf{V}_0|^2 + M \mathbf{r}_{\text{CM}} \cdot (\mathbf{V}_0 \times \boldsymbol{\Omega}) + \frac{1}{2} \boldsymbol{\Omega} \hat{I}_0 \boldsymbol{\Omega}$$

where \mathbf{V}_0 is the velocity of the chosen reference point O , $\mathbf{r}_{\text{CM}} = \mathbf{R}_{\text{CM}} - \mathbf{r}_O$ is the position of the CM with respect to O , and $\boldsymbol{\Omega}$ is the angular velocity of the body.

Moment of Inertia:

$$I_{xx}^{(0)} = \int_V \rho(\mathbf{r})(y^2 + z^2) dV \quad I_{xy}^{(0)} = \int_V \rho(\mathbf{r})xy dV$$

Parallel Axis Theorem:

$$I_{xx}^{(0)} = I_{xx}^{\text{CM}} + M(d_y^2 + d_z^2)$$
